UNOBSERVANTIVE JAVASCRIPT

Keeping JavaScript out of HTML
Announcements

- Demo Tuesday, March 25
  - Design
    - Sketch of pages to be implemented
    - Notes on what the pages do
  - Backlog
    - $5 \times$ number of team member stories
    - E.g.
      - Four member team needs 20 stories
      - Five member team needs 25 stories
      - Six member team needs 30 stories
I left out Databases

- Will introduce them today
- Slides added to subsequent lessons
Why Unobtrusive JavaScript

- To keep files of different languages separate
- HTML: Describes the content to be presented
- CSS: Describes the content format
- PHP: Describes how to create a web page
- JavaScript: Describes response to user input
- SQL: Describe elements of the data
Web Languages

- Local hardware
  - HTML
  - CSS
- Responsiveness
  - JavaScript

- Data
  - PHP
  - SQL
HTTP Origin (1990’s)

1. Designed to share scientific papers (Memex)
   - Request a paper and it is returned.
2. Extended to support multimedia (Mime)
   - Request any media and it is returned.
3. Extended to support interactivity (CGI, JavaScript)
   - Add more details to your request.
Client-Server Programming (1990s)

- Client is a program that requests information from the server and displays it to the user.
- Server provides the information when requested.
- Both the client and the server were large programs:
  - The client needed to deal with all of the problems of displaying information and sending information back to the server.
  - The server needed to store all of the information and provide the business logic.
HTTP Today

- A full featured client-server system with a division of concerns
  - Browser (client) knows the local hardware.
    - HTML describes the content
    - CSS provide information of formatting intent
    - JavaScript provides interactivity within the content
  - Web Server provides the content when requested
    - PHP prepares the content from Data on the Server
    - Captures the business logic of the site.
Keeping the languages separate

- Important for clarity of expression: you are expressing different things with the different languages.

- HTML, CSS and JavaScript live in different files
  - HTML must provides classes and IDs for elements that are manipulated by CSS.
  - HTML must provide IDs for element that have events for JavaScript.

- PHP is difficult to separate out
  - Use functions to name activities
Keeping the languages separate 2

- PHP is difficult to separate out
  - Use functions to name activities
  - Use include to break up files
  - Keep HTML restricted to certain files
Database Basics

- 13.1: Database Basics
- 13.2: SQL
- 13.3: Multi-table Queries
- 13.4: Databases and PHP
Relational Databases

- **relational database**: A method of structuring data as tables associated to each other by shared attributes.

- A table row is a unit of data called a record; a column is an attribute of that record.

- A Database Management System (DBMS) is a program that manages databases.

- DBMS’s often use Structured Query Language (SQL) to define, manage, and search relational data.
Why use a database

- Powerful: search, filter, combine data
- Fast: search, filter faster than from a file
- Big: scale well up to very large data sizes
- Safe: mechanisms for failure recovery (e.g. transactions)
- Multi-user: many users view/edit data at same time
- Layer of abstraction between data and app(s)
  - Many database programs understand the same SQL commands

Quiz

1. What information does the window object contain?
2. Why do you need to attach event handlers to events using the window.onload event?
3. What is an anonymous function?
4. What does the keyword “this” refer to?
And the answer is ...
Quiz Answers

1. What information does the window object contain?
   1. The default information about windows such as the height, width …

2. Why do you need to attach event handlers to events using the window.onload event?
   1. So that the window will load before the handlers are attached to the events. Otherwise, the events may not be there.

3. What is an anonymous function?
   1. A function without a name e.g. function () {} }

4. What does the keyword “this” refer to?
   1. The current object.
Chapter 9.1

Unobtrusive JavaScript
## The six global DOM objects

<table>
<thead>
<tr>
<th>name</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>document</td>
<td>current HTML page and its content</td>
</tr>
<tr>
<td>history</td>
<td>list of pages the user has visited</td>
</tr>
<tr>
<td>location</td>
<td>URL of the current HTML page</td>
</tr>
<tr>
<td>navigator</td>
<td>info about the web browser you are using</td>
</tr>
<tr>
<td>screen</td>
<td>info about the screen area occupied by the browser</td>
</tr>
<tr>
<td>window</td>
<td>the browser window</td>
</tr>
</tbody>
</table>
The window object

- the entire browser window; the top-level object in DOM hierarchy

- technically, all global code and variables become part of the window object properties:
  - document, history, location, name

- methods:
  - alert, confirm, prompt (popup boxes)
  - setInterval, setTimeout clearInterval, clearTimeout (timers)
  - open, close (popping up new browser windows)
  - blur, focus, moveBy, moveTo, print, resizeBy, resizeTo, scrollBy, scrollTo
The document object

- the current web page and the elements inside it

- properties:
  - anchors, body, cookie, domain, forms, images, links, referrer, title, URL

- methods:
  - getElementById
  - getElementsByName
  - getElementsByTagName
  - close, open, write, writeln
The location object

- the URL of the current web page

- properties:
  - host, hostname, href, pathname, port, protocol, search

- methods:
  - assign, reload, replace
The navigator object

- information about the web browser application
- properties:
  - appName, appVersion, browserLanguage, cookieEnabled, platform, userAgent
- Some web programmers examine the navigator object to see what browser is being used, and write browser-specific scripts and hacks:

```javascript
if (navigator.appName === "Microsoft Internet Explorer") {
  ...
}
```
The screen object

- information about the client’s display screen

- properties:
  - availHeight, availWidth, colorDepth, height, pixelDepth, width
The history object

- the list of sites the browser has visited in this window

- properties:
  - length

- methods:
  - back, forward, go

- sometimes the browser won't let scripts view history properties, for security
Unobtrusive JavaScript

- JavaScript event code seen previously was *obtrusive*, in the HTML; this is bad style
- now we'll see how to write unobtrusive JavaScript code
  - HTML with minimal JavaScript inside
  - uses the DOM to attach and execute all JavaScript functions
Unobtrusive JavaScript

- allows separation of web site into 3 major categories:
  - content (HTML) - what is it?
  - presentation (CSS) - how does it look?
  - behavior (JavaScript) - how does it respond to user interaction?
Obtrusive event handlers (bad)

- this is bad style (HTML is cluttered with JS code)
- goal: remove all JavaScript code from the HTML body
Attaching an event handler in JavaScript code

- it is legal to attach event handlers to elements' DOM objects in your JavaScript code
  - notice that you do not put parentheses after the function's name
- this is better style than attaching them in the HTML
- Where should we put the above code?
When does my code run?

- your file's JS code runs the moment the browser loads the script tag
  - any variables are declared immediately
  - any functions are declared but not called, unless your global code explicitly calls them
When does my code run?

- at this point in time, the browser has not yet read your page's body
  - none of the DOM objects for tags on the page have been created
A failed attempt at being unobtrusive

- problem: global JS code runs the moment the script is loaded
- script in head is processed before page's body has loaded
  - no elements are available yet or can be accessed yet via the DOM

```html
<head>
  <script src="myfile.js" type="text/javascript"></script>
</head>
<body>
  <div><button id="ok">OK</button></div>
</body>
```

```javascript
// global code
$("ok").onclick = okayClick; // error: $("ok") is null
```
The `window.onload` event

- We want to attach our event handlers right after the page is done loading.
- There is a global event called `window.onload` event that occurs at that moment.
- In `window.onload` handler we attach all the other handlers to run when events occur.

```javascript
// this will run once the page has finished loading
function functionName() {
    element.event = functionName;
    element.event = functionName;
...
}
window.onload = functionName; // global code
```
An unobtrusive event handler

<!-- look Ma, no JavaScript! -->
<button id="ok">OK</button>

// called when page loads; sets up event handlers
function pageLoad() {
    $('ok').onclick = okayClick;
}
function okayClick() {
    alert("booyah");
}
window.onload = pageLoad; // global code
Common unobtrusive JS errors

- Event names are all lowercase, not capitalized like most variables.

```javascript
window.onload = pageLoad();
okButton.onclick = okayClick();
```

```javascript
window.onLoad = pageLoad;
window.onload = pageLoad;
```
Anonymous functions

function(parameters) {
    statements;
}

- JavaScript allows you to declare anonymous functions
- quickly creates a function without giving it a name
- can be stored as a variable, attached as an event handler, etc.
Anonymous function example

```javascript
window.onload = function() {
    var okButton = document.getElementById("ok");
    okButton.onclick = okayClick;
};
function okayClick() {
    alert("booyah");
}
```
The keyword `this`

```
this.fieldName // access field
this.fieldName = value; // modify field
this.methodName(parameters); // call method
```

- all JavaScript code actually runs inside of an object
- by default, code runs inside the global `window` object
  - all global variables and functions you declare become part of `window`
- the `this` keyword refers to the current object
The keyword `this`
Fixing redundant code with `this`
Example: Tip Calculator

```html
<h1>Tip Calculator</h1>
<div>
  $<input id="subtotal" type="text" size="5" /> subtotal

  <button id="tenpercent">10%</button>
  <button id="fifteenpercent"> 15%</button>
  <button id="eighteenpercent"> 18%</button>

  <span id="total"></span>
</div>
```

```js
window.onload = function() {
  $("tenpercent").onclick = computeTip;
}

function computeTip{
  var subtotal = parseFloat($("subtotal").value);
  var tipAmount = subtotal*0.1; //Add this code
  $("total").innerHTML = "Tip: $" + tipAmount;
}
```
