Western New York Theory Day May 2, 2008

Based on: "Splay Trees, Davenport-Schinzel Sequences, and the Deque Conjecture", Seth Pettie, SODA, January 2008

## Binary Search Tree - Search Operation

Search of target key $z \rightarrow$ walk down from the root
Cost of search $=\operatorname{depth}(z)+1$

## Search Problem

Given binary search tree $T_{0}$ and a sequence of target keys $X=\left\{x_{1}, x_{2}, x_{3}, \ldots . x_{m}\right\}$

Search for and locate each key at total minimal cost

## Balanced Binary Search Trees

height of tree $=O(\log n)$
$\begin{array}{ll}\text { AVL (height balanced) } & \begin{array}{l}\text { Drawbacks: } \\ \\ \\ \text { Red-black }\end{array} \\ & \text { •Not adaptive: } X=\{1,1,1,1,1, \ldots .1\}\end{array}$

$$
\text { cost }=O(m \log n)
$$

$$
\text { optimal cost }=0(n+m)
$$

## Alter Tree Shape using Rotations

We can alter the shape of the tree by rotating an edge

```
-constant time operation
```

-preserves symmetric order
-changes the depths of some nodes in the tree

## Search Problem using Rotations

Given binary search tree $T_{0}$ and a sequence of target keys $X=\left\{x_{1}, x_{2}, x_{3}, \ldots . x_{m}\right\}$

OPT $\left(T_{0}, X\right)=$ cost of the sequence of rotations and searches which minimize the total cost

Nodes higher in the tree are cheaper to find

## Locality of Reference Principle

Target key $\mathbf{X}$ of a search is likely to be a target of another search in near future

So move $\mathbf{X}$ to the root to make subsequent searches faster
(e.g., LRU, cache, working set)

## Splay Tree

No limit on the shape of the tree

Reshape the tree after each search to move the target key to the root

## Splay Tree

Zig case: odd number of edges on path final rotation is of edge ( $\mathrm{x}_{\mathrm{i}}$, root $)$

Zig-zig case:

Zig-zag case:

## Before and After

## Sequential Access Case

Most extreme initial tree, height $=\mathrm{n}$
sequence of target keys $X=\{1,2,3,4, \ldots . n\}$

## Sequential Access Case

node 1 rotates to the root using repeated "zig-zigs"

## Sequential Access Case

node 2 rotates to the root
using repeated "zig-zigs"

## Sequential Access Case

node 3 rotates to the root using repeated "zig-zigs"

## Sequential Access Case

Splay trees are "building in balance" automatically

## Splay trees match Balanced trees

"•"•"•

Claim: Splay trees behave very well over the entire sequence of operations.

Theorem (Sleator and Tarjan, 1985): Given binary search tree $T_{0}$ and a sequence of target keys $X=\left\{x_{1}, x_{2}, x_{3}, \ldots x_{m}\right\}$, the total cost of performing these searches is $\mathbf{O}(\mathbf{m} \boldsymbol{\operatorname { l o g }} \mathbf{n})$

## Dynamic Optimality

A binary search tree algorithm $\mathbf{A}$ is dynamically optimal if for every $\left(T_{0}, X\right)$

$$
\operatorname{cost}_{A}\left(T_{0}, X\right) \leq \operatorname{coPT}\left(T_{0}, X\right)
$$

for some constant c .

Conjecture (Sleator and Tarjan, 1985): Splay trees are dynamically optimal.

## Corollaries of Dynamic Optimality

- Static Optimality Theorem (1985): Let $q_{i}$ be the number of times $i$ is accessed, then the total access time for splay trees is $O\left(m+\sum q_{i} \log \left(m / q_{i}\right)\right)$
- Working Set Theorem (1985): Let $\mathrm{t}_{\mathrm{j}}$ be the number of distinct items accessed between the last access of $i(j)$, and the current access, then the total access time for splay trees is $O\left(n \log n+m+\sum \log \left(t_{j}+1\right)\right)$
- Dynamic Finger Theorem (2000): the total access time for splay trees is $\mathrm{O}\left(m+\sum \log (|i(j)-i(j+1)|+1)\right.$

## What Access Sequences are Easy?

- Static Optimality Theorem (1985): Let $q_{i}$ be the number of times $i$ is accessed, then the total access time for splay trees is $\mathrm{O}\left(m+\sum \mathrm{q} \cdot \log \left(\mathrm{m} / \mathrm{q}_{\mathrm{i}}\right)\right)$
- Working Set Theorem (1985): Let $\mathrm{t}_{\mathrm{j}}$ be the number of distinct items accessed between the last access of $j$, and the current access, then the total access time for splay trees is $\left.O\left(n \log n+m+\quad \log \left(t_{2}\right)+1\right)\right)$
- Dynamic Finger Theorem (2000): the total access time for splay trees is $\mathrm{O}\left(m+\sum \log (\mathrm{D}) \mathrm{i}(\mathrm{j})-\mathrm{i}(\mathrm{j}+1) \mid+1\right)$
- Sequential Access Theorem (1985): The total time for $X=$ $\{1,2,3, \ldots n\}$ is $(\mathrm{O}(\mathrm{n})$ )

## Unfolding a Tree into Vine

Any tree can be unfolded into a left vine using at most ( $\mathrm{n}-1$ ) rotations

The left vine tree can be folded into any tree using at most ( $\mathrm{n}-1$ ) rotations

## Sequential Access is Easy

OPT $\left(T_{0}, X\right) \leq(n-1)+n-1=O(n)$
when $X=\{1,2,3,4,5, \ldots . n\}$

Theorem (Tarjan 1985): Given binary search tree $T_{0}$ the total cost of performing a sequence of n accesses in sequential order is $\mathbf{O ( n )}$

## Deque Access

Deque (double-ended queue)

Access each element once in an "from the outside in" fashion

$X=\{1,9,8,2,3,7,4,5,6\}$

## Deque Access is Easy

OPT $\left(T_{0}, X\right) \leq(2 n-2)+1+2(n-2)=O(n)$

Theorem (Sundar 1992): Given binary search tree $T_{0}$ the total cost of performing a sequence of $n$ deque-ordered accesses is $\mathbf{O}(\mathbf{n a ( n )})$

Ackermann's function:

$$
A_{1}(j)=2 j

## New Result

OPT $\left(T_{0}, X\right) \leq(2 n-2)+1+2(n-2)=O(n)$

Theorem (Sundar 1992): Given binary search tree $T_{0}$ the total cost of performing a sequence of $n$ deque-ordered accesses is $\mathbf{O}(\mathbf{n} \mathbf{a}(\mathbf{n}))$

Theorem (Pettie 2008): Given binary search tree $T_{0}$ the total cost of performing a sequence of $n$ deque-ordered accesses is $\mathbf{O}\left(\mathbf{n} \mathbf{a}^{*}(\mathbf{n})\right.$ )

## What is the cost of deque-splaying?

WLOG : Splay is "spinal" along the left-path (not necessarily to the root)

## Sundar: divide-and-conquer

## Sundar: divide-and-conquer

Each block corresponds to a well-defined sub-tree

## Sub-problem rotations

Each rotation is either entirely inside a sub-problem, forming a "deque splaying" operation in that sub-problem

## Or cross-block rotations

## Accounting for cross-block rotations

We need to account for the rotations that are between sub-problems

Shrink every sub-problem into a single node, at the common ancestor of all nodes in that block.

## Global sub-problem

Set the parent of each "block subtree root" to be the nearest black ancestor

This creates a well-defined binary search tree of these "block roots"

## How does a splay effect global sub-problem?

## Seth Pettie (2008): $\alpha$ to $\alpha$ *

NEW TECHNIQUE using Davenport-
OPT $\left(\mathrm{T}_{0}, \mathrm{X}\right) \leq(2 \mathrm{n}-2)+1+2(\mathrm{n}-2)=\mathrm{O}(\mathrm{n})$
Schinezel sequences

Theorem (Sundar 1992): Given binary search tree $T_{0}$ the total cost of performing a sequence of $n$ deque-ordered accesses is $\mathbf{O}(\mathbf{n a ( n )})$

Theorem (Pettie 2008): Given binary search tree $T_{0}$ the total cost of performing a sequence of $n$ deque-ordered accesses is $\mathbf{O}\left(\mathbf{n} \mathbf{a}^{*}(\mathbf{n})\right)$

## Davenport-Schinzel Sequences (1965)

A s-DS sequence is any finite sequence

$$
\mathrm{u}=\mathrm{a}_{1} \mathrm{a}_{2} \mathrm{a}_{3} \mathrm{a}_{4} \ldots . . \mathrm{a}_{1}
$$

over the infinite alphabet $A=\{1,2,3,4, \ldots$.$\} such that:$

- u has no immediate repetitions

- u does not contain a sub-sequence isomorphic to $v=$ abababa, (i.e., no alternating sub-sequence of length s)

## Extremal function $\lambda_{s}(n)$

$$
\lambda_{\mathrm{s}}(\mathrm{n})=\max \{|\mathrm{u}|: \mathrm{u} \text { is an }(\mathrm{s}+2) \text {-DS sequence and }\|\mathrm{u}\| \leq \mathrm{n}\}
$$

What is the longest sequence you can form, using only $n$ symbols, with no immediate repetitions, and avoiding the sub-sequence aba.....ba?

$\mathrm{s}+2$

## Extremal function $\lambda_{2}(3)$

$\lambda_{2}(3)=\max \{|\mathrm{u}|: \mathrm{u}$ is an 4-DS sequence and $\| \mathrm{u}| | \leq 3\}$

What is the longest sequence you can form, using only 3 symbols, with no immediate repetitions, and avoiding the sub-sequence abab?

$\lambda, 1,12,121,1213,12131,123,1231,1232,12321$

## Geometric application

Consider the "lower envelope" of these segments

## Geometric application

Label each region by the line segment $\mathrm{S}_{\mathrm{i}}$ that is minimal on that region

## Geometric application

Sequence: 2, 1, 2, 3, 2, 3, 1, 3 cannot contain subsequence "ababa"

## $\lambda_{3}(n)$ is complexity of lower envelope

$\lambda_{3}(n)=\max \{|u|: u$ is a $5-D S$ sequence and $\|u\| \leq n\}$
$\lambda_{s}(n)$

$\lambda_{s}(n)=$ complexity when the $S_{i}$ can intersect $\leq(s-2)$ times

## $\lambda_{2}(n)$ is linear

Theorem (Davenport-Schnizel 1965): $\lambda_{2}(n)=2 n-1$
The longest possible sequence using $n$ symbols, with no immediate repetition and avoiding the sub-sequence abab, has length $2 n-1$

Proof: $2 n-1 \leq \lambda_{2}(n) \leq 2 n-1$
$\lambda_{2}(n) \geq 2 n-1 \quad \rightarrow \quad 1,2,3, \ldots \ldots . n-1, n, n-1, \ldots \ldots . .2,1$

## Agarwal, Sharir, and Shor (1989)

What is the longest sequence you can form, using only $n$ symbols, with no immediate repetitions, and avoiding the sub-sequence aba.....ba?

|  | $\lambda_{1}(\mathrm{n})$ | n |
| :---: | :---: | :---: |
|  | $\lambda_{2}(\mathrm{n})$ | 2n-1 |
|  | $\lambda_{3}(\mathrm{n})$ | $\Theta(\mathrm{n} \alpha \mathrm{n})$ ) |
|  | $\lambda_{4}(\mathrm{n})$ | $\Theta\left(\mathrm{n} 2{ }^{(0)}\right)$ |
| $\Omega\left(\mathrm{n} 2^{\text {a }}\right.$ ( $) ~(~) ~$ | $\lambda_{5}(\mathrm{n})$ | $\mathrm{O}\left(\mathrm{n} \alpha(\mathrm{n})^{(1+o(1)) \alpha(\mathrm{n})}\right)$ |
| $\mathrm{O}\left(\mathrm{n} 2^{(1+o(1)) a(n)^{2} / 2}\right)$ | $\lambda_{6}(\mathrm{n})$ | $\mathrm{O}\left(\mathrm{n} 2^{\left.(1+o(1)) \mathrm{a}(\mathrm{n})^{2}\right)}\right.$ |

## Deque Splaying

If $X$ is a deque-ordered sequence, then

$$
\mathrm{OPT}\left(\mathrm{~T}_{0}, \mathrm{X}\right)=\mathrm{O}(\mathrm{n})
$$

Theorem (Sundar 1992): Given binary search tree $\mathrm{T}_{0}$ the total cost of performing a sequence of $n$ deque-ordered accesses is $\mathbf{O}(\mathbf{n} \mathbf{a}(\mathbf{n})$ )

Theorem (Pettie 2008): Given binary search tree $T_{0}$ the total cost of performing a sequence of $n$ deque-ordered accesses is $\mathbf{O}\left(\mathbf{n} \mathbf{a}^{*}(\mathbf{n})\right)$

Proof: Characterize the cost of Deque Splaying as a Davenport-Schnizel sequence, then cut-andpaste the results of Agarwal et. al.

## Describe rotations as DS sequence

Same idea of dividing nodes into consecutive sub-problems

Non-sub-problem nodes that are touched by a splay from a node in sub-problem j are "affiliated" with j

## Describe rotations as DS sequence

Non-sub-problem nodes that are touched by a splay from a node in sub-problem j are "affiliated" with j

Node receives this label if no ancestor is in the same block, or has the same affiliation.

## Describe rotations as DS sequence

Non-sub-problem nodes that are touched by a splay from a node in sub-problem j are "affiliated" with j

Node receives this label if no ancestor is in the same block, or has the same affiliation.

## Describe rotations as DS sequence

Non-sub-problem nodes that are touched by a splay from a node in sub-problem j are "affiliated" with j

Node receives this label if no ancestor is in the same block, or has the same affiliation.

Multiple labels on a node are given in descending order
$\qquad$ $3,1,2, \ldots \ldots$

## Forbidden sub-sequence babba

Cannot have second appearance of ' $b$ ' after the appearance of an 'a'
$\qquad$ b .... a ..... b $\qquad$ b $\qquad$ a $\qquad$

## Forbidden sub-sequence babba

## Deque Splaying

If $X$ is a deque-ordered sequence, then OPT $\left(T_{0}, X\right)=O(n)$

Theorem (Sundar 1992): Given binary search tree $T_{0}$ the total-cost of performing a sequence of $n$ deque-ordered accesses is ( $\mathbf{n}$ a ( $n$ ) )

Theorem (Pettie 2008): Given binary search tree $T_{0}$ the total coct of performing a sequence of $n$ deque-ordered accesses is ( $\mathbf{n} \mathbf{a}^{*}(\mathbf{n})$ )

Proof: Characterize the cost of Deque Splaying as a Davenport-Schnizel sequence, then cut-and-paste the results of Agarwal et. al.

Improvements? Use generalized DS sequences (with known linear bounds)?

## Generalized DS Sequences

$E x(v, n)=\max \{|u|: u$ does not contain $v$,

$$
\begin{aligned}
& \mathrm{u} \text { is }\|\mathrm{v}\| \text { regular, } \\
& \text { and }\|\mathrm{u}\| \leq \mathrm{n}\}
\end{aligned}
$$

What is the longest sequence you can form, using only $n$ symbols, with no symbol repetition in any \|v\| substring, and avoiding the sub-sequence $v$ ?

Theorem (Klazar, 1995) : Ex(abba, $n$ ) $=O(n)$
Ex(abcdabcd, n) $=O(n)$
$E x(a a b b c c a a b b c c, n)=O(n)$

Open Problem: $\quad$ Ex $(a b a c a b c, n)=$ ??? Linear? Super-linear?
