

Time Complexity Classes

Measuring Complexity

Complexity of a problem = **the efficiency of the best algorithm for the problem**

Measure the efficiency by **time** or **space**, or both

Analyze the efficiency by the **growth of the function that relates the amount of resources used to the input size**

Worst-case analysis ... analyze the function that maps each nonnegative integer n to the *maximum amount of resources used for solving any input of size n* with the best algorithm known

An alternative is **average case analysis**

An example: $L = \{0^n 1^n \mid n \geq 0\}$

Algorithm A, for a 1-tape TM

Match and erase the outermost non-blank symbols

Notation: C : the symbol currently scanned

$[H \Rightarrow]$ ($[H \Leftarrow]$) : moving the head to the right (left) by one cell

The Main Loop:

1. **if $C = \sqcup$ then accept ; if $C = 1$ then reject**
2. $C \leftarrow \sqcup$
3. **repeat $[H \Rightarrow]$ until $C = \sqcup$;**
4. $[H \Leftarrow]$; **if $C \neq 1$ then reject ; $C \leftarrow \sqcup$**
5. **repeat $[H \Leftarrow]$ until $C = \sqcup$; $[H \Rightarrow]$**

Big-O, small-o

Definition. Let $f, g : \mathcal{N} \rightarrow \mathcal{R}^+$ be two functions.

- $f = O(g)$ if there exists a constant $c > 0$ such that for all but finitely many n , $f(n) \leq cg(n)$.
- $f = o(g)$ if $\lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = 0$.

Example: $\log n = o(n)$, $\log n \log n = o(n)$, $10n + 8 \log n = O(n)$, etc.

Note: $f = o(g)$ implies $f = O(g)$, but the converse does not necessarily hold

The running time of Algorithm A is $O(n^2)$

Can do in $O(n)$ steps if two tapes are available

Algorithm B, for a 2-tape TM

Copy the first run of 0s onto Tape 2 and measure the length of the following run of 1s

Notation: C_i , $[H_i \Rightarrow]$, $[H_i \Leftarrow]$, $i = 1, 2$

1. (the initial check)

if $C_1 = \sqcup$ then accept ; if $C_1 = 1$ then reject

2. put the left marker

$C_2 \leftarrow \#; [H_2 \Rightarrow]$

3. (copying the first block)

while $C_1 = 0$ do

- $C_2 \leftarrow 0; [H_1 \Rightarrow]; [H_2 \Rightarrow]$

4. **if $C_1 = \sqcup$ then reject ;**

5. **(comparing the length)**

while $C_1 = 1$ do

• **if $C_2 = \#$ then reject ; $[H_1 \Rightarrow]$; $[H_2 \Leftarrow]$;**

6. **if $C_1 = \sqcup$ and $C_2 = \#$ then accept ; else reject**

Algorithm B runs in $n + 1 = O(n)$ steps.

Deterministic Time Complexity Classes

Definition. Let $t : \mathcal{N} \rightarrow \mathcal{N}$ be a function. A Turing machine M is $t(n)$ time (or $t(n)$ time-bounded) if for every $n \in \mathcal{N}$, and for every input x of length n , M on x halts within $t(n)$ steps.

Definition. Let $t : \mathcal{N} \rightarrow \mathcal{N}$ be a function. Define $\text{TIME}(t(n)) = \{L \mid L \text{ is decided by an } O(t(n)) \text{ time multi-tape Turing machine}\}$.

$L = \{0^n 1^n \mid n \geq 1\}$ is in $\text{TIME}(n)$, the **linear time** complexity class

Nondeterministic Time Complexity Classes

Definition. Let $t : \mathcal{N} \rightarrow \mathcal{N}$ be a function. A nondeterministic Turing machine N is $t(n)$ time if for every $n \in \mathcal{N}$, and for every input x of length n , N on x halts within $t(n)$ steps along all computation paths.

Definition. Let $t : \mathcal{N} \rightarrow \mathcal{N}$ be a function. Define $\text{NTIME}(t(n)) = \{L \mid L \text{ is decided by an } O(t(n)) \text{ time nondeterministic multi-tape Turing machine}\}$.

Relationships Among Models

Theorem. *For every $t(n) \geq n$, each $t(n)$ time multi-tape Turing machine has an equivalent $t(n)^2$ time single-tape Turing machine.*

Theorem. *For every $t(n) \geq n$, each $t(n)$ time nondeterministic Turing machine has an equivalent $2^{O(t(n))}$ time single-tape Turing machine.*
