

# Network Layer Overview

Kai Shen

2/6/2013 CSC 257/457 - Spring 2013 1

## Internet Architecture

Bottom-up:

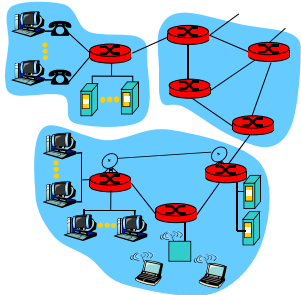

- **physical:** electromagnetic signals “on the wire”
- **link:** data transfer between neighboring network elements
  - encoding, framing, error correction, access control for shared links
- **network:** host-to-host connectivity
  - routing, addressing
- **transport:** host-host data transport
  - reliable data transport, congestion control, flow control
- **application:** anything you want to do on computer networks

application
transport
network
link
physical

2/6/2013 CSC 257/457 - Spring 2013 2

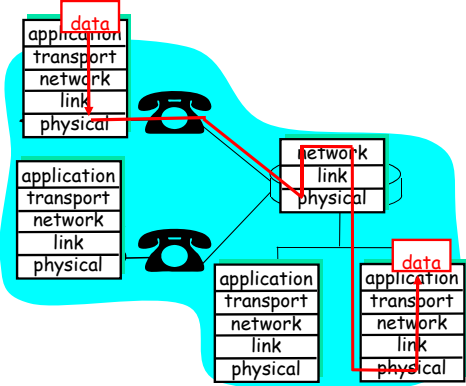

## Network Layer Function

- transport packet from sending to receiving hosts
  - **addressing:** uniquely identify each node in the network
  - **routing:** determine a path from source to dest and route packets along the path
- network connecting devices
  - called “routers”
  - participate in network protocols
- links
  - connect adjacent hosts, routers

2/6/2013 CSC 257/457 - Spring 2013 3

## Protocol Layers and Data Flows

2/6/2013 CSC 257/457 - Spring 2013 4

### Data Formation Across Layers

Each layer takes data from above

- adds header information to create new data unit
- passes new data unit to layer below

2/6/2013 CSC 257/457 - Spring 2013 5

### Network Service Model

- loss-free delivery?
- in-order delivery?
- preservation of inter-packet delay (no jitter)?
- guaranteed bandwidth?
- congestion feedback to sender?

connection-based or packet switching?

2/6/2013 CSC 257/457 - Spring 2013 6

### Connection-based Networks

- guaranteed bandwidth, jitter-free, in-order delivery build on the concept of connections, or virtual circuits
- require signaling protocols to setup, maintain, and teardown virtual circuit
- router maintains state about ongoing connections

2/6/2013 CSC 257/457 - Spring 2013 7

### Packet Switching

- no connection ⇒ every packet is on its own
- stateless routers ⇒ no need to remember anything about packets
- packets forwarded independently from each other
  - packets between same source-dest pair may take different paths

2/6/2013 CSC 257/457 - Spring 2013 8

## Packet Switching vs. Connection-based Networks

### Packet switching

- poor service guarantee
    - “elastic” service
  - efficiency
  - scalability
  - robustness
  - flexibility/customization
    - simple network core, complexity at “edge”
- ⇒ manage, control, adapt at “smart” end systems (computers)

### Connection-based

- evolved from telephony
- guaranteed service
  - e.g., human conversation: strict timing, reliability requirements
- hard to evolve
  - complex network core

Internet employs packet switching; connection-based are more suitable for networks with “dumb” end terminals - telephones.

## Routing Principles

### Routing protocol

Goal: determine “good” path (sequence of routers) thru network from source to dest.

Graph abstraction for routing algorithms:

- graph nodes are hosts or routers
- graph edges are links
  - link cost: delay, \$ cost, or congestion level
- “good” path:
  - typically means minimum cost path

2/6/2013

CSC 257/457 - Spring 2013

10

## Routing Algorithm Classification

### Global information:

- all routers have complete topology, link cost info
- “link state” algorithm

### Decentralized:

- router knows connected neighbors, link costs to neighbors
- exchange of info with neighbors to learn remote parts of the network, may take many learning rounds
- “distance vector” algorithm

11

## A Link-State Routing Algorithm

### Dijkstra’s algorithm

- Network topology, link costs/distances known to all nodes
  - accomplished via “link state broadcast”
  - all nodes have same info
- The algorithm calculates the shortest paths from one specific node (“source”) to all other nodes
- **Basic approach:** gradually expands a set “N”, containing nodes whose shortest paths from the source are known
  - initially “N” contains only the source itself
  - at every step one more node’s shortest path from the source is learned, this node is then added to “N”
  - eventually “N” includes every node and the algorithm terminates

2/6/2013

CSC 257/457 - Spring 2013

12

### Dijkstra's Algorithm (cont.)

"N", containing nodes with known shortest paths from source

**Key step:** How to expand "N" to include one more node?

- "1-more-hop paths":
  - paths from source to dest. v (not in N) whose last hop before v is in N *How to find them?*
  - D(v) as the distance of the shortest 1-more-hop path to v
- For arbitrary v, is D(v) shortest path distance to v?
- For v\* with shortest D(v) among all v's not in N, D(v\*) is the shortest path distance to v\*.

2/6/2013 CSC 257/457 - Spring 2013 13

### Dijkstra's Algorithm: An Example

- N**: set of nodes whose shortest paths are currently known
- D(v)**: distance for shortest 1-more-hop path from source to dest. v
- p(v)**: predecessor node along path from source to dest. v

Step	N	D(B),p(B)	D(C),p(C)	D(D),p(D)	D(E),p(E)	D(F),p(F)
→ 0	A	2,A	5,A	1,A	infinity	infinity
→ 1	AD	2,A	4,D		2,D	infinity
→ 2	ADE	2,A	3,E			4,E
→ 3	ADEB		3,E			4,E
→ 4	ADEBC					4,E
5	ADEBCF					

2/6/2013 CSC 257/457 - Spring 2013 14

### Dijkstra's Algorithm: Complexity

**Algorithm complexity:** n nodes, e links

- Each iteration: need to check all nodes, v, not in N  
 ⇒  $n*(n-1)/2$  checks:  $O(n^2)$
- Update 1-more-hop paths:  $O(e)$
- Total:  $O(n^2+e)$ , or  $O(n^2)$
- Using Fibonacci heap to find minimum distance node  
 ⇒  $O(n \log n + e)$

2/6/2013 CSC 257/457 - Spring 2013 15

### Dijkstra's Algorithm: Stability

**Oscillations possible:**

- e.g., link cost = amount of carried traffic

**Solutions:**

- asynchronous (at different time) adjustments across routers
- stable cost metric (independent of routing policy)
