GOOD	LUCK!!!

Problem 0: Warm-up (2 Points)					
Who do you usually st	udy CSC 252	with?			
Problem 1: Fixed-Pe Part a) (4 points) Re					
Part b) (4 points) R	epresent the l	binary value 111	0110111 in he	xadecimal.	
Part c) (4 points) Octal value 273 in bina		e-8 number sys	stem, and uses	s the digits o to 7.	Represent the
Part d) (3 points) St shown below.	uppose the re	gisters % esi , %	ebx, and %ed	x are initialized w	ith the values
%esi	%€	ebx		%edx (before)	
0xA2E058	OX	800		охо	
What would the value	of % edx be af	ter the instruct	ion: lea (%e	esi, %ebx, 8),	%edx?

Part e) (3 points extra credit) Let A and B be two unknown 8-bit 2's complement numbers. We know the results of A ^ B and A & B as shown below:

A ^ B	00110100
A & B	11001001

(1 point) What is the sum A + B expressed in the 8-bit two's complement notation?

On an x86 system, would the carry flag be set after A + B? What about the overflow flag?

Will carry flag be set? (1 point)	
Will overflow flag be set? (1 point)	

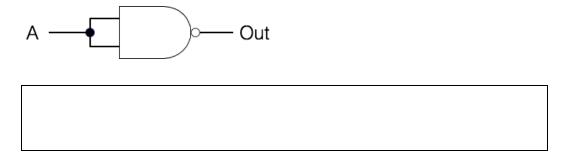

Problem 2: Floating-Point Arithmetics (16 points + 2 points extra credit)	
Part a) (4 points) Put $4\frac{3}{16}$ in binary normalized form.	
Part b) (12 points + 2 points extra credits) In this problem, we assume that IEEE do to add a new 12-bit representation, with its main characteristics consistent with the other standards.	
In this 12-bit representation, the value 155/256 is represented exactly as 001000110110.	
(4 points) How many bits are needed for exponent?	
(4 points) How many bits are needed for fraction?	
(4 points) In this 12-bit representation, what is the smallest positive number that can be	:
represented?	
(2 points extra credit) You want to calculate the sum of the following three numbers the	
represented using this 12-bit floating point format: (A) 110111100100, (B) 010101110000,	and
(C) 011011000000. Give an order in which the addition will generate the expected sum.	

Problem 3: Logic Design (14 points)

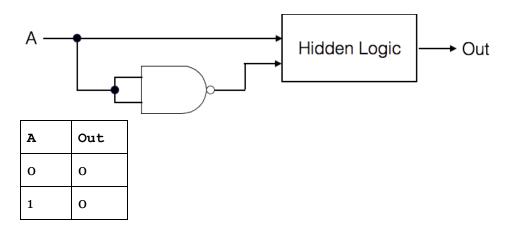

The following is the schematic of a NAND gate, which takes in two 1-bit inputs **A** and **B**, and generates one 1-bit output **Out**. The NAND gate functions in such a way that **Out** = ! (**A** & **B**).

Part a) (3 points) Now we build the following piece of combinational logic using the NAND gate, which takes in one 1-bit input A, and generates one 1-bit output Out. What's the relationship between Out and A?

Part b) (11 points) We have the combinational circuit shown below with part of its logic hidden. It takes in one 1-bit input: A, and produces one 1-bit output: Out. The relationship between A and Out is shown in the accompanying truth table.

(3 points) What is the functionality of the hidden logic in the circuit? You can denote the two inputs to the hidden logic as In1 and In2.

(5 points) Implement the hidden logic using only NAND gates. Draw its scheme	natic below.
(3 points) Given your above implementation and assuming the delay of a NAN what is the delay of the entire combinational circuit?	D gate is 1ps,

Problem 4: Assembly Programming (14 points + 6 points extra credits)

Below is the assembly code for a mystery function in C. Assume this function takes in an unsigned integer from 1 ~ 8 in %edi and returns a value to %eax. The function prototype is the following: unsigned int mystery (unsigned int);

Assembly code:

```
0 \times 0 0 0 0 0 0 0 0 0 0 0 4 0 0 5 5 6 <+0>:
                              push
                                       %rbp
0 \times 00000000000400557 <+1>:
                                       %rsp,%rbp
                              mov
0x000000000040055a <+4>:
                                       $0x10,%rsp
                               sub
0 \times 00000000000040055e <+8>:
                                       %edi,-0x4(%rbp)
                              mov
0 \times 000000000000400561 < +11>: cmpl
                                       $0x2,-0x4(%rbp)
0 \times 000000000000400565 < +15 > : ine
                                       0x40056e < mystery + 24 >
0 \times 000000000000400567 < +17>: mov
                                       $0x2, %eax
0x000000000040056c <+22>:
                                       0x4005a5 < mystery + 79 >
                              qmŗ
0x000000000040056e <+24>: cmpl
                                       $0x1,-0x4(%rbp)
0 \times 000000000000400572 < +28 > : jq
                                       0x400583 < mystery + 45 >
0 \times 000000000000400574 <+30>: mov
                                       -0x4(%rbp),%eax
0 \times 000000000000400577 < +33 > : sub
                                       $0x1, %eax
0 \times 00000000000040057a < +36 > : mov
                                       %eax,%edi
0x00000000040057c <+38>: callq 0x400556 <mystery>
0 \times 000000000000400581 < +43>: jmp
                                       0x4005a5 < mystery + 79 >
0x00000000000400583 < +45>: cmpl
                                       $0x1,-0x4(%rbp)
0x0000000000400587 <+49>:
                              jle
                                       0x4005a5 < mystery + 79 >
0 \times 000000000000400589 < +51 > : mov
                                       -0x4(%rbp), %eax
0x0000000000040058c < +54>: sub
                                       $0x2, %eax
0x0000000000040058f <+57>: mov
                                       %eax,%edi
0x000000000400591 <+59>: callq 0x400556 <mystery>
0 \times 000000000000400596 < +64>: imul
                                       -0x4(%rbp),%eax
0x0000000000040059a <+68>: mov
                                       -0x4(%rbp),%edx
0x0000000000040059d <+71>: sub
                                       $0x1, %edx
0 \times 000000000004005a0 < +74>: imul
                                       %edx, %eax
0x00000000004005a3 < +77>: jmp
                                       0x4005a5 < mystery + 79 >
0x00000000004005a5 <+79>: leaveq
0x00000000004005a6 <+80>:
                              retq
```

Part a) (4 points) Assume 2 is stored in <code>%edi</code> at the beginning of the function execution. Which lines of assembly will have been executed after the function finishes execution (denote as			
function offset e.g. <+24>)?			
are these values? Recall that the input is an unsigned integer from 1 ~	8 stored in %edi.		
Part c) (5 points) For the input values that do not cause integer over this function return? Please express it as a closed-form function of the the input as x).	-		

make the function work for all input values 1 ~ 8. What is one set of 3 or fewer lines of changes you can make? Note that deletion and replacement are valid changes, insertion is not.
Line# (denote as function offset):

Part d) (6 points extra credit) There are some ways to modify this assembly program to

Problem 5: ISA and Microarchitecture (14 points + 9 points extra credits)

Suppose you are working for a microprocessor company RoCChip. You take on the job of designing the ISA and microarchitecture for a new computer. You want the ISA to have two types of instructions detailed below.

The first type of instructions (Type A) has the following general format: Opcode Ra, Rb, Imm

Instructions of this type operate as follows. We perform an operation between the values in registers Ra and Rb, and store the result to the memory address specified by the immediate value Imm. The immediate value is treated as an absolute (as opposed to relative) memory address. The exact operation to be performed between Ra and Rb depends on the specific Opcode.

The binary encoding for this type of instructions is the following. The most significant bit is always 0, indicating that that this is a Type A instruction.

0	Opcode Ra	Rb	Imm
---	-----------	----	-----

The second type of instructions (Type B) has the following general format:

Opcode Ra, Rb, Rc

Instructions of this type operate as follows. We perform an operation between the values in registers Ra and Rb, and store the result to the memory address specified by value in register Rc. Similarly, the exact operation to be performed between Ra and Rb depends on the specific Opcode.

The binary encoding for this type of instructions is the following. The most significant bit is always 1, indicating that that this is a Type B instruction.

1	Opcode	Ra	Rb	Rc
	_			

You want your machine to be byte addressable (i.e., each addressable memory location is one byte, just like x86). The total memory capacity is 2²⁰ Bytes. Each register in this machine hold 4 bytes of data.

For each instruction type, you plan to support 8 different arithmetic and logic operations (same 8 for each type). You also have the limitation that the length of Type A instructions must be 4 bytes.

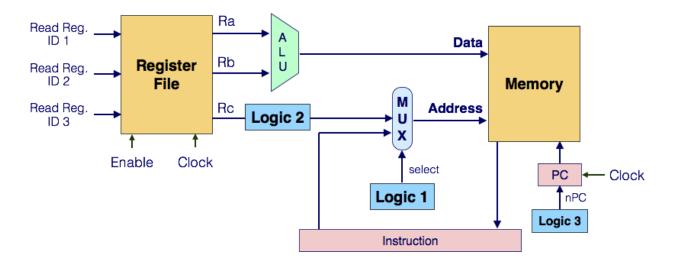

Part a) (3 points) What is the minimum number of bits to represent the Opcode field in both
types of instructions?
Part b) (3 points) What is the minimum number of bits to represent the Imm field in Type A?
Part c) (4 points) Using the number of bits for Opcode and Imm that you came up with in (a) and (b), what is the maximum number registers that your ISA can support?
and (b), what is the maximum number registers that your 1511 can support.
Part d) (4 points) Assume that we have a program with 1000 instructions. 20% of them are of
Type A, and 80% of Type B. How much space in the memory is occupied by this program?

<u>Part e) (9 points extra credit)</u> Now that you finish designing the ISA, you start working on the microarchitecture, which only has to support the two types of instructions. Below is the partially complete schematic of the microarchitecture.

The "Address" port of the memory takes the memory address to be written to, and the "Data" port of the memory takes the data to be written to the memory.

The register file has three read ports and can read three registers, Ra, Rb, and Rc, simultaneously. How the three Read Reg. IDs are generated is irrelevant to this problem.

There are three hidden logics in this partially complete microarchitecture. You job: determine the functionalities of the three hidden logics. Note that not all the input signals to the logics are shown. You need to figure out what signals each logic needs.

(3 points) Logic 1 generates the select signal to the MUX that produces the memory address. Briefly explain how Logic 1 generates the select signal.

(3 points) Logic 2 takes the value of Rc and generates one of the two pieces of data that go into the MUX. Briefly explain how Logic 2 generates its output.

(3 points) Logic 3 generates the next PC (nPC), which contains the address of the next instruction to be fetched and executed. Briefly explain how Logic 3 generates nPC.							
nstruction to be fet	ched and execu	ited. Briefly e	xplain how Lo	gic 3 generate	es nPC.
