What if your program is an
operating system kernel?

Operating Systems are Just Programs

- ❖ Code has global, stack, and heap like other programs
- ❖ Code manipulates data structures like other programs

Operating System is a Special Program

- ❖ Privileged hardware configuration
 - ❖ Page tables
 - ❖ Interrupt Vector Table
- ❖ State manipulation
 - ❖ Context switching
 - ❖ Signal handler dispatch

Challenge 1: Assembly Code

- ❖ Assembly code is hand-written
- ❖ Very difficult to analyze
- ❖ The value of LLVM is that you avoid binary analysis

Challenge 2: Memory with Side Effects

- ❖ Loads and stores access the following
 - ❖ Memory objects (global, stack, heap)
 - ❖ Page tables
 - ❖ Interrupt vector tables
 - ❖ Interrupted Program State
 - ❖ State saved on context switch

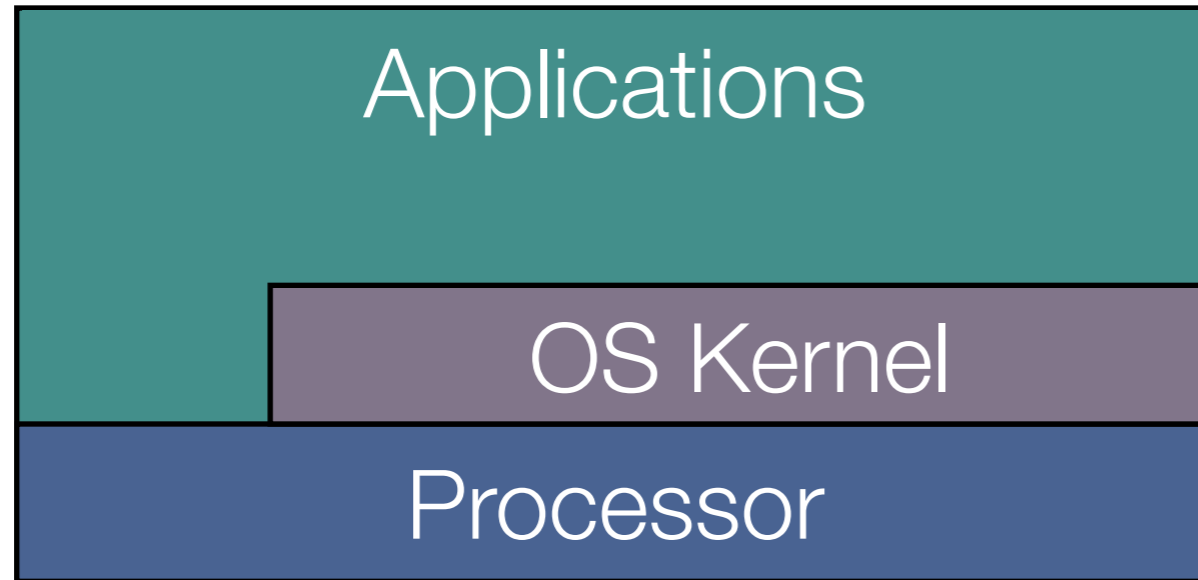

Stores to Memory

- ❖ Does store to memory modify control flow?

pt_regs or trapframe

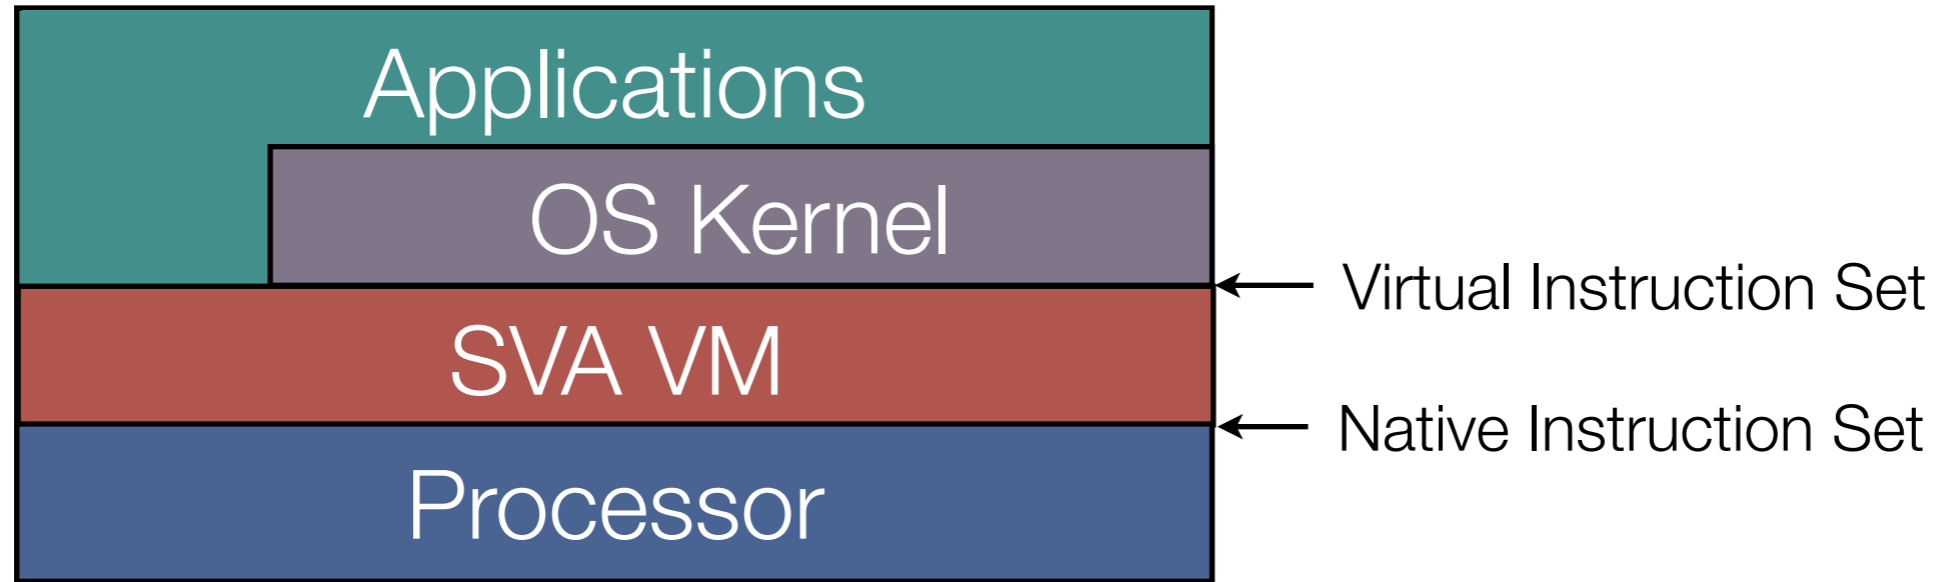

Secure Virtual Architecture

- ❖ OS compiled to virtual instruction set
 - ❖ Designed to be easy to analyze and instrument
 - ❖ Low-level instructions (SVA-OS) replace assembly code
- ❖ Translate ahead-of-time, boot-time, or run-time

Secure Virtual Architecture

- ❖ OS compiled to virtual instruction set
 - ❖ Designed to be easy to analyze and instrument
 - ❖ Low-level instructions (SVA-OS) replace assembly code
- ❖ Translate ahead-of-time, boot-time, or run-time

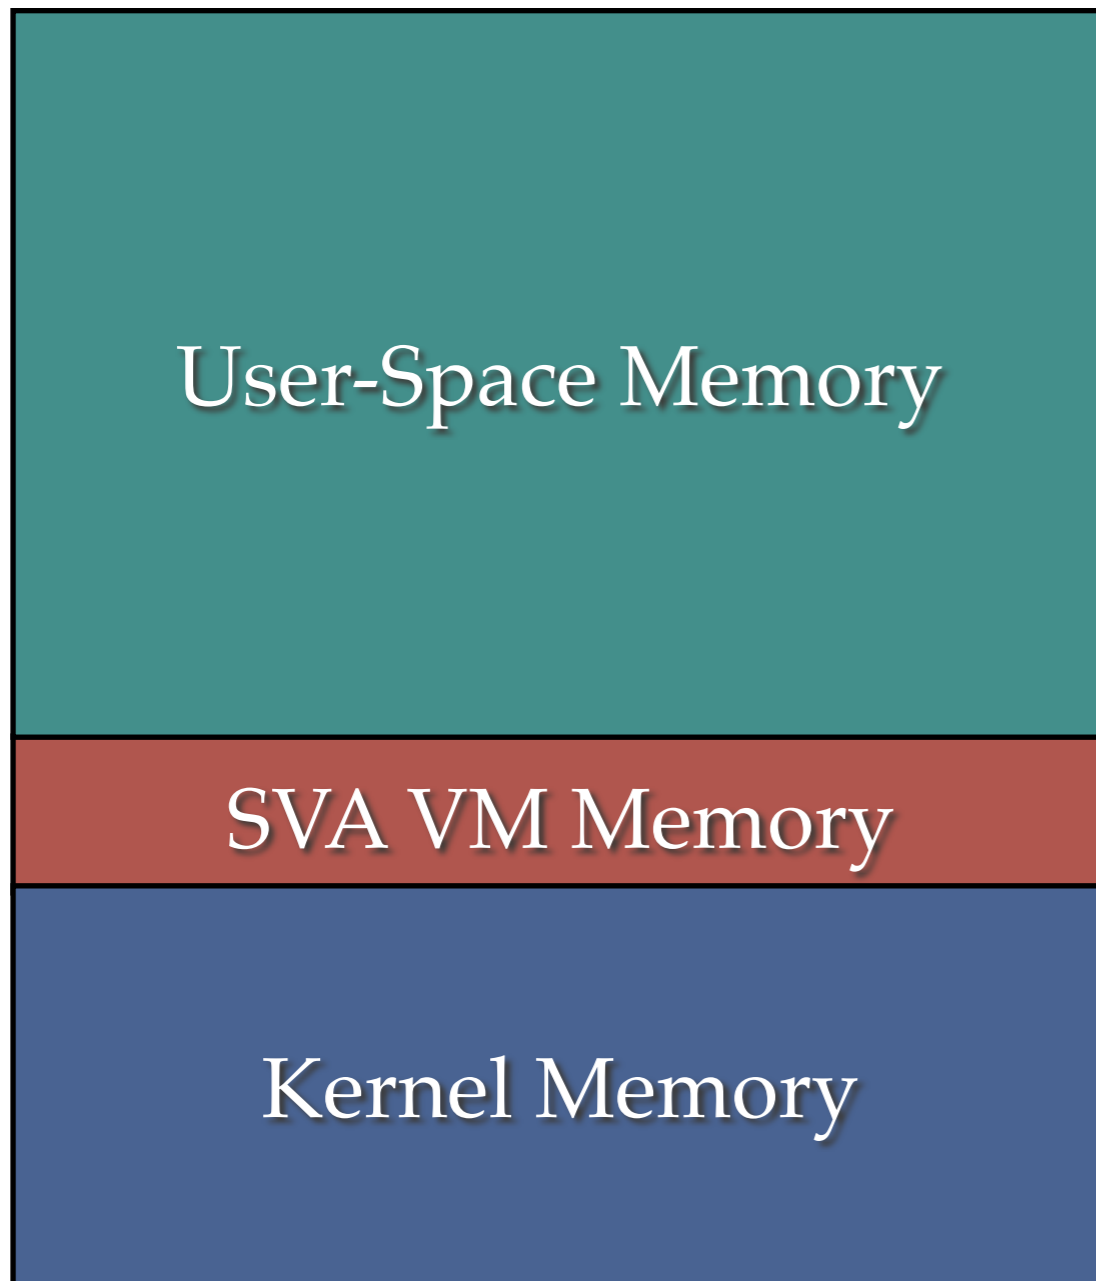

SVA Virtual Instruction Set

- ❖ SVA-Core: Compiler Instrumentation
 - ❖ Based on LLVM IR: Typed, Explicit SSA form
- ❖ SVA-OS: SVA Runtime
 - ❖ OS-neutral instructions to support a commodity OS
 - ❖ Encapsulates & controls hardware and state manipulation

SVA Virtual Address Space Layout

- ❖ Store opaque state in SVA VM memory
- ❖ Protect SVA VM memory from corruption
 - ❖ Memory safety
 - ❖ SFI

State Saved in SVA VM Memory

- ❖ Privileged hardware state
 - ❖ Interrupt vector table
 - ❖ System call table
 - ❖ Page table pages
- ❖ Program state
 - ❖ State saved on context switch
 - ❖ State saved on interrupt, trap, system call

Opaque Native State

State	Purpose
Integer State	Represents the native state on the CPU
Interrupt Context	Represents native state saved on an interrupt, trap, or system call

SVA-OS Instructions

Handler Registration

Function	Description
<code>sva.register.interrupt()</code>	Register interrupt handler
<code>sva.register.trap()</code>	Register trap handler
<code>sva.register.syscall()</code>	Register system call handler

MMU Configuration

Function	Description
<code>sva.declare.ptp()</code>	Mark memory as page table page
<code>sva.update.mapping()</code>	Modify entry in a page table page
<code>sva.release.ptp()</code>	Remove page from page table page
<code>sva.mm.load.pagetable()</code>	Load page table pointer on to CPU
<code>sva.mm.save.pagetable()</code>	Save copy of page table pointer on CPU

State Manipulation Instructions

Function	Description
<code>sva.swap.integer()</code>	Context switch to a new thread
<code>sva.new.thread()</code>	Create new thread
<code>sva.icontext.save()</code>	Save interrupt context on to thread interrupt context stack
<code>sva.icontext.load()</code>	Load interrupt context on thread interrupt stack
