Previous lecture

- Previous lecture
 - Concrete Semantics for a Small Language
- Today:
 - Value abstractions
 - Non-relational Abstractions
 - Abstract Semantics
 - Soundness, termination, etc.

Outline

Recap

Value Abstractions

Computable Abstract Semantics

Postscript

Abstraction Examples

- Consider the concrete memory state M :
 - $\{\{x \mapsto 7, y \mapsto 2\}, \{x \mapsto 8, y \mapsto 0\}\}$
 - How shall we abstract it?
- $x = \{7, 8\}$
 - Signs: $x = [\geq 0]$
 - Intervals: $x = [7, 8]$
- $y = \{0, 2\}$
 - Signs: $y = [\geq 0]$
 - Intervals: $y = [0, 2]$ (note: $[0, 2] = \{0, 1, 2\}$)
- Alternatively:
 - Signs: $x = \top$ (here, $\top = \mathbb{V} = \mathbb{Z}$)
 - Intervals: $y = [0, 3]$
 - Multiple abstractions are possible, but some are less precise

Lattice for Signs Domain

- Signs, $\mathbb{A}_{\mathcal{S}} = \{\top, [\leq 0], [\geq 0], [= 0], \perp\}$
 - $\top = \mathbb{V}$ (recall $\mathbb{V} = \mathbb{Z}$ for our language)
 - $[\leq 0] = \{x \mid x \leq 0\}$
 - $[\geq 0] = \{x \mid x \geq 0\}$
 - $[= 0] = \{0\}$
 - $\perp = \emptyset$
- Order relation \sqsubseteq
 - Items *lower* in the lattice are more precise
 - $a \sqsubseteq b$, read as a less than b
- Join \sqcup
 - Least upper bound, lub

Lattice for Intervals Domain

- Intervals, $\mathbb{A}_{\mathcal{I}} =$
 $\{\top, \perp\} \cup \{[n, m] \mid n, m \in \mathbb{Z}\}$
 - $\top = (-\infty, +\infty) = \mathbb{V} = \mathbb{Z}$
 - $[n, m] = \{x \mid n \leq x \leq m\}$
 - $[n, +\infty) = \{x \mid n \leq x\}$
 - $(-\infty, m] = \{x \mid x \leq m\}$
 - $\perp = \emptyset$
- Infinite lattice
- Order relation \sqsubseteq and Join \sqcup supported

Abstraction and Concretization Functions (Informal)

- Given an element c of the concrete domain \mathbb{C} , we want $a \in \mathbb{A}$
 - c is a set of values
 - e.g. $x = \{7, 8\}$
- Let the value abstraction function be ϕ_γ
 - $\phi_\gamma : \mathbb{C} \rightarrow \mathbb{A}$
- Similarly, given an abstract element $a \in \mathbb{A}$, we want the concrete element c corresponding to it
 - e.g., $a = [\leq 0] \in \mathbb{A}_{\mathcal{G}}$
 - So, corresponding $c = \{\dots, -3, -2, -1, 0\}$
- Let this value concretization function be γ_γ
 - $\gamma_\gamma : \mathbb{A} \rightarrow \mathbb{C}$
- Key questions: how do we relate ϕ_γ to γ_γ
 - soundly,
 - precisely?

Code for Signs

```
class SignsDomain(object):
    LTZ = "[<= 0]"
    GTZ = "[>= 0]"
    EQZ = "[= 0]"
    TOP = "TOP"
    BOT = "BOT"
    finite_height = True

    def phi(self, v: int):
        if v == 0:
            return self.EQZ
        elif v > 0:
            return self.GTZ
        elif v < 0:
            return self.LTZ
        else:
            raise ValueError(f"Unknown value for signs abstraction {v}")
```

```

class SignsDomain(object):
    ...
    # it helps to think of abstract elements as sets, with lte
    # denoting set inclusion. So we're asking, is x included in y?
    def lte(self, x, y):
        # bot is always less than everything else
        # empty set {} is always included
        if x == self.BOT: return True

        # top is only lte
        # top is all possible values, so it is only included in itself
        if x == self.TOP:
            if y != self.TOP: return False
            return True

        # eqz is the set {0}, which is included in all sets ( $\geq 0$ ,  $\leq 0$ ) except {}
        if x == self.EQZ:
            if y == self.BOT: return False
            return True

        if x == self.LTZ or x == self.GTZ:
            if y == x: return True
            if y == self.TOP: return True

        # these sets are not included in {0} or {} or  $\{ \geq 0 \}$  [resp.  $\{ \leq 0 \}$ ]
        return False

```

```
class SignsDomain(object):
    ...
    def lub(self, x, y):
        if self.lte(x, y): return y # y includes x
        if self.lte(y, x): return x # x includes y

        # if incomparable, then we return T
        return self.TOP
```

Concrete Domains

- Values in our concrete domain belong to $\wp(\mathbb{M})$
 - Recall $\mathbb{M} = \mathbb{X} \rightarrow \mathbb{V}$
- A concrete domain is the pair (\mathbb{C}, \subseteq)
 - $\mathbb{C} = \wp(\mathbb{M})$
 - If $x, y \in \mathbb{C}$, and $x \subseteq y$, then x implies y
 - x and y are behavioural properties expressed as sets
 - x is at least as “strong” as y
- Example:
 - x is set of all states where $x > 10$
 - y is set of all states where x is non-negative
 - Clearly $x \subseteq y$

Abstraction

- An abstract domain is $(\mathbb{A}, \sqsubseteq)$
 - \sqsubseteq orders members of \mathbb{A}
- An abstraction relation $(\models) \subseteq \mathbb{C} \times \mathbb{A}$, such that:
 - for all $c \in \mathbb{C}, a_0, a_1 \in \mathbb{A}$, if $c \models a_0$, and $a_0 \sqsubseteq a_1$, then $c \models a_1$
 - example: $c = \{0\}$, $a_0 = [= 0]$, $a_1 = [\geq 0]$ in the signs domain
 - for all $c_0, c_1 \in \mathbb{C}, a \in \mathbb{A}$, if $c_0 \subseteq c_1$ and $c_1 \models a$, then $c_0 \models a$
 - example: $c_0 = \{3, 5\}$, $c_1 = \{2, 3, 4, 5, 6\}$, $a = [2, 6]$
- The goal of abstraction is to map $c \in \mathbb{C}$ to the most precise $a \in \mathbb{A}$

Concretization Function

- $\gamma_{\mathcal{V}} : \mathbb{A} \rightarrow \mathbb{C}$, the concretization function is defined as:
 - $\gamma_{\mathcal{V}}(a) \models a$,
 - $\gamma_{\mathcal{V}}(a)$ is the maximum concrete element of \mathbb{C} that satisfies a
 - I.e., if $\gamma_{\mathcal{V}}(a) = c$, there no other c' such that $c' \models a$ and $c \subseteq c'$
- Examples:
 - $\gamma_{\mathcal{G}}([\leq 0]) = \{x \mid x \leq 0\}$
 - $\gamma_{\mathcal{G}}([0, 3]) = \{0, 1, 2, 3\}$
 - $\gamma(\perp) = \emptyset$
- Concretization can be used instead of \models to define the abstraction relation:
 - $\forall c \in \mathbb{C}, a \in \mathbb{A} \quad c \models a \iff c \subseteq \gamma_{\mathcal{V}}(a)$
 - e.g.: using signs, $c = \{3\}$, $a = [\geq 0]$, $\gamma_{\mathcal{V}}(a) = \{0, 1, 2, 3, 4, \dots\}$

(Best) Abstraction Function

- $\alpha : \mathbb{C} \rightarrow \mathbb{A}$, the abstraction function is defined as:
 - $c \models \alpha(c)$
 - $\alpha(c)$ is the minimum element of \mathbb{A} that is satisfied by c
 - i.e., if $\alpha(c) = a$, there is no other a' such that $c \models a'$ and $a' \sqsubseteq a$
- Examples:
 - $\alpha_{\mathcal{F}}(\{0\}) = [= 0]$
 - $\alpha_{\mathcal{F}}(\{0, 3\}) = [0, 3]$
- α may not exist

When α may not exist

- When $[= 0]$ is removed from signs, it has no best abstraction function
 - $\{0\}$ can be described by either $[\leq 0]$ or $[\geq 0]$
 - $[\leq 0] \not\subseteq [\geq 0]$ and $[\geq 0] \not\subseteq [\leq 0]$
- Convex polyhedra
 - No finite set of linear inequalities can approximate a circle (in the 2-D domain) or its equivalents in higher domains
 - Each linear equality is a tangent to the circle

Galois Connections

- When α_{γ} exists:

$$\forall c \in \mathbb{C}, a \in \mathbb{A}, \alpha_{\gamma}(c) \sqsubseteq a \iff c \sqsubseteq \gamma_{\gamma}(a)$$

- The pair γ_{γ} and α_{γ} form a Galois connection with the following properties:
 - γ_{γ} and α_{γ} are monotone
 - $\forall c \in \mathbb{C}, c \sqsubseteq \gamma_{\gamma}(\alpha(c))$
 - $\forall a \in \mathbb{A}, \alpha_{\gamma}(\gamma_{\gamma}(a)) \sqsubseteq a$

Non-relational Abstraction #1

- A non-relational abstraction does not capture relationships between variables
 - Each variable is abstracted independently
- We can extend the value abstraction functions we've defined so far to define a non-relational abstraction:
 - M^\sharp is the abstraction of M
 - $M \subseteq \gamma_{\mathcal{N}}(M^\sharp)$
- The concretization function is defined as:
 - $\gamma_{\mathcal{N}} : M^\sharp \mapsto \{m \in \mathbb{M} \mid \forall \mathbf{x} \in \mathbb{X}, m(\mathbf{x}) \in \gamma_{\mathcal{V}}(M^\sharp(\mathbf{x}))\}$
- The order relation $\sqsubseteq_{\mathcal{V}}$ is pointwise-extended:
 - $M_0^\sharp \sqsubseteq^\sharp M_1^\sharp$ if and only if $\forall \mathbf{x} \in \mathbb{X}, M_0^\sharp(\mathbf{x}) \sqsubseteq_{\mathcal{V}} M_1^\sharp(\mathbf{x})$

Non-relational Abstraction #2

- The bottom $\perp_{\mathcal{N}}$ is defined as:
 - $\forall \mathbf{x} \in \mathbb{X}, \perp_{\mathcal{N}}(\mathbf{x}) = \perp_{\gamma}$
- The abstraction function, if it exists, is defined as:
 - $\alpha_{\mathcal{N}} : M \mapsto (\mathbf{x} \in \mathbb{X}) \mapsto \alpha_{\gamma}(\{m(x) \mid m \in M\})$

Code Implementation for a Non-relational Abstraction

```
class NonRelationalAbstraction(object):
    def __init__(self, domain):
        self.dom = domain

    def phi(self, M):
        m_accum = {}

        for m in M:
            m_abs = {}
            for x in m:
                m_abs[x] = self.dom.phi(m[x])

            if len(m_accum) == 0:
                m_accum = m_abs
            else:
                m_accum = self.union(m_accum, m_abs)

        # also construct BOT
        self.BOT = {}
        for x in m_accum:
            self.BOT[x] = self.dom.BOT

        return m_accum

    def lte(self, MO_abs, M1_abs):
        for x in MO_abs:
            if not self.dom.lte(MO_abs[x], M1_abs[x]): return False

        return True
```

Outline

Recap

Value Abstractions

Computable Abstract Semantics

Postscript

Goal: Sound Static Analysis

Goal: Sound Static Analysis

$$\begin{array}{ccc} a_{\text{pre}} & \xrightarrow{\llbracket p \rrbracket_{\mathcal{P}}^{\#}} & a_{\text{post}} = \llbracket p \rrbracket_{\mathcal{P}}^{\#}(a_{\text{pre}}) \\ \uparrow \in \gamma(\cdot) & & \uparrow \in \gamma(\cdot) \\ m & \xrightarrow{\llbracket p \rrbracket_{\mathcal{P}}} & m' \end{array}$$

Abstraction of empty set

Recall:

$$\llbracket C \rrbracket(\emptyset) = \emptyset$$

so we will define:

$$\llbracket C \rrbracket_{\mathcal{D}}^{\#}(\perp) = \perp$$

In code:

```
def evaluate_Cmd_abs(C: Cmd, M_abs: AbstractMemory, abstraction) -> AbstractMemory:
  ...

  if M_abs == abstraction.BOT:
    return M_abs

  ...
```

$$\llbracket \text{skip} \rrbracket_{\mathcal{D}}^{\#}(M^{\#}) = M^{\#}$$

In code:

```
def evaluate_Cmd_abs(C: Cmd, M_abs: AbstractMemory, abstraction) -> AbstractMemory:
    ...

    # the value abstraction
    v_abs = abstraction.dom

    if isinstance(C, Skip):
        return M_abs
    elif isinstance(C, Program):
        return evaluate_Cmd_abs(C.program, M_abs, abstraction)
    ...
```

$$\llbracket C_0; C_1 \rrbracket_{\mathcal{P}}^{\sharp}(M^{\sharp}) = \llbracket C_1 \rrbracket_{\mathcal{P}}^{\sharp}(\llbracket C_0 \rrbracket_{\mathcal{P}}^{\sharp}(M^{\sharp}))$$

- This seems to be intuitive, but we need to show that:
 - The concrete postcondition of $\llbracket C_0; C_1 \rrbracket_{\mathcal{P}}$ is over-approximated by $\llbracket C_0; C_1 \rrbracket_{\mathcal{P}}^{\sharp}$
 - I.e. $\llbracket C_0; C_1 \rrbracket_{\mathcal{P}} \subseteq \gamma(\llbracket C_0; C_1 \rrbracket_{\mathcal{P}}^{\sharp})$

Theorem: Approximation of Compositions: Let

$F_0, F_1 : \wp(\mathbb{M}) \rightarrow \wp(\mathbb{M})$ be two monotone functions that are overapproximated by $F_0^{\sharp}, F_1^{\sharp} : \mathbb{A} \rightarrow \mathbb{A}$, i.e. $F_0 \circ \gamma \subseteq \gamma \circ F_0^{\sharp}$ and $F_1 \circ \gamma \subseteq \gamma \circ F_1^{\sharp}$. Then, $F_0 \circ F_1$ can be approximated by $F_0^{\sharp} \circ F_1^{\sharp}$

Composition in Code

```
def evaluate_Cmd_abs(C: Cmd, M_abs: AbstractMemory, abstraction) -> Abstra
...
elif isinstance(C, Seq):
    return evaluate_Cmd_abs(C.cmd1,
                            evaluate_Cmd_abs(C.cmd0, M_abs,
                                              abstraction),
                            abstraction)
...
```

$$\llbracket E \rrbracket^\# : \mathbb{A} \rightarrow \mathbb{A}_\gamma$$

$$\llbracket n \rrbracket^\#(M^\#) = \phi_\gamma(n)$$

$$\llbracket \mathbf{x} \rrbracket^\#(M^\#) = M^\#(\mathbf{x})$$

$$\llbracket E_0 \odot E_1 \rrbracket^\#(M^\#) = f_{\odot}^\#(\llbracket E_0 \rrbracket^\#(M^\#), \llbracket E_1 \rrbracket^\#(M^\#))$$

- ϕ_γ can be replaced by α_γ if it exists
 - Otherwise just return an abstract element such that $\{n\} \subseteq \gamma(\phi_\gamma(n))$

Expressions: f_{\odot}^{\sharp}

$$\forall n_0^{\sharp}, n_1^{\sharp} \in \mathbb{A}_{\gamma}, \{f_{\odot}(n_0, n_1) \mid n_0 \in \gamma_{\gamma}(n_0^{\sharp}) \text{ and } n_1 \in \gamma_{\gamma}(n_1^{\sharp})\} \subseteq \gamma_{\gamma}(f_{\odot}^{\sharp}(n_0^{\sharp}, n_1^{\sharp}))$$

- The result of applying $f_{\odot}^{\sharp}(n_0^{\sharp}, n_1^{\sharp})$, when concretized
 - $\gamma_{\gamma}(f_{\odot}^{\sharp}(n_0^{\sharp}, n_1^{\sharp}))$
- must include the concrete set formed when we apply f_{\odot} to ...
- ... the elements of the individual concretizations of $n_0^{\sharp}, n_1^{\sharp}$
 - $n_0 \in \gamma_{\gamma}(n_0^{\sharp})$
 - $n_1 \in \gamma_{\gamma}(n_1^{\sharp})$

Examples (using signs):

- $f_{+}^{\sharp}([\geq 0], [\geq 0]) = [\geq 0]$
- $f_{+}^{\sharp}([\geq 0], [\leq 0]) = \top$

Expressions: $f_{\odot}^{\#}$ in code (Signs)

```
def f_binop(self, op, left, right):
    if op == '+':
        return self.lub(left, right)
    elif op == '*':
        if left != right:
            return self.lub(left, right)
        elif left == self.LTZ:
            return self.GTZ # - * - = +
        elif left == self.GTZ:
            return self.GTZ # + * + = +
    elif op == '-':
        if left == right:
            if left != self.EQZ and left != self.BOT:
                return self.TOP

            return left # {0} - {0} => {0}, {} - {} => {}
        else:
            return left # {+ve} - {-ve} => {+ve}, {-ve} - {+ve} => {-ve}
    else:
        raise NotImplementedError(f'Operator {op}')
```

- $f_{\odot}^{\#}$ is per abstract domain (not per language as in the concrete semantics)

Expressions: f_{\ominus}^{\sharp} in code (Intervals)

See `f_binop` in `dom_intervals.py`.

- The tricky aspects revolve around handling $-\infty$ and $+\infty$

Assignments and `input`

The concrete semantics are:

$$\llbracket x := E \rrbracket_{\mathcal{C}}(M) = \{m[x \mapsto \llbracket E \rrbracket(m)] \mid m \in M\}$$

The abstract semantics are:

$$\llbracket x := E \rrbracket_{\mathcal{A}}^{\#}(M^{\#}) = M^{\#}[x \mapsto \llbracket E \rrbracket^{\#}(M^{\#})]$$

Similarly, since `input` also writes to a variable:

$$\llbracket \text{input}(x) \rrbracket_{\mathcal{A}}^{\#}(M^{\#}) = M^{\#}[x \mapsto \top_{\psi}]$$

Recall that `input` can return any value from the user.

Assignments and input Code

```
def evaluate_Cmd_abs(C: Cmd, M_abs: AbstractMemory, abstraction) -> AbstractMemory:
    def update_abs_memories(var, value_lambda):
        out = dict(M_abs)
        out[var] = value_lambda(M_abs)
        return out

    ...

    elif isinstance(C, Assign):
        return update_abs_memories(C.left.name,
                                   lambda m: evaluate_Expr_abs(C.right,
                                                                m, v_abs))

    elif isinstance(C, Input):
        return update_abs_memories(C.var.name, lambda _: v_abs.TOP)

    ...
```

Conditionals: Example

```
# M# = {x: T, y: T}
x := 7
# M# = {x: [7, 7], y: T}

if (x > 5)
  # M# = {x: [6, +inf), y: T}
  y = 1
  # M# = {x: [6, +inf), y: [1, 1]}
else
  # M# = {x: (-inf, 5], y: T}
  y = 10
  # M# = {x: (-inf, 5], y: [10, 10]}

# M# = {x: [-inf, +inf], y: [1, 10]}
```

- We need a abstract filtering function \mathcal{F}_B^\sharp
 - Its effects are shown
- We need to join the abstract elements:
 - Use the lub (least upper bound), here \sqcup^\sharp
- But we have lost precision for x !

```
# M# = {x: T, y: T}
x := 7
# M# = {x: [7, 7], y: T}

if (x > 5)
  # M# = {x: [7, 7], y: T}
  y = 1
  # M# = {x: [7, 7], y: [1, 1]}
else
  # M# = {x: BOT, y: BOT}
  y = 10
  # M# = {x: BOT, y: BOT}

# M# = {x: [7, 7], y: [1, 1]}
```

- For the true part, $[6, +\infty)$ is refined to $[7, 7]$
- For the false part, $(-\infty, 5]$ does not include $[7, 7]$
 - So the abstract state $M^\#$ is refined to \perp , by setting all variables to \perp
 - Recall that $\llbracket C \rrbracket_{\mathcal{F}}^\#(\perp) = \perp$ and that $a \sqcup^\# \perp = a$

Soundness properties

For \mathcal{F}_B^\sharp : For all B and abstract states M^\sharp

$$\mathcal{F}_B(\gamma(M^\sharp)) \subseteq \gamma(\mathcal{F}_B^\sharp(M^\sharp))$$

For \sqcup^\sharp over M_0^\sharp and M_1^\sharp :

$$\gamma(M_0^\sharp) \cup \gamma(M_1^\sharp) \subseteq \gamma(M_0^\sharp \sqcup^\sharp M_1^\sharp)$$

Abstract Semantics of If

$$\llbracket \text{if}(B)\{C_0\} \text{ else } \{C_1\} \rrbracket_{\mathcal{D}}^{\#}(M^{\#}) = \llbracket C_0 \rrbracket_{\mathcal{D}}^{\#}(\mathcal{F}_B^{\#}(M^{\#})) \sqcup^{\#} \llbracket C_1 \rrbracket_{\mathcal{D}}^{\#}(\mathcal{F}_{\neg B}^{\#}(M^{\#}))$$

Code:

```
def evaluate_Cmd_abs(C: Cmd, M_abs: AbstractMemory, abstraction) -> AbstractMemory:
    ...
    elif isinstance(C, IfThenElse):
        then_memory, else_memory = filter_memory_abs(C.cond, M_abs, v_abs)

        then_memory = evaluate_Cmd_abs(C.then_, then_memory, abstraction)
        else_memory = evaluate_Cmd_abs(C.else_, else_memory, abstraction)

        ite_memory = abstraction.union(then_memory, else_memory)

    return ite_memory
```

Code for filter_memory_abs

```
def filter_memory_abs(B: BoolExpr, M_abs: AbstractMemory, vabs) ->
  Tuple[AbstractMemory, AbstractMemory]:
  true_abs, false_abs = evaluate_BoolExpr_abs(B, M_abs, vabs)
  var_abs = M_abs[B.left.name]

  true_abs = vabs.refine(var_abs, true_abs)

  if true_abs != vabs.BOT:
    # may enter true part
    M_abs_true = dict(M_abs)
    M_abs_true[B.left.name] = true_abs
  else:
    M_abs_true = dict([(m, vabs.BOT) for m in M_abs])

  false_abs = vabs.refine(var_abs, false_abs)

  if false_abs != vabs.BOT:
    # may enter false part
    M_abs_false = dict(M_abs)
    M_abs_false[B.left.name] = false_abs
  else:
    M_abs_false = dict([(m, vabs.BOT) for m in M_abs])

  return M_abs_true, M_abs_false
```

Partial code for f_cmpop and refine in the Intervals domain

```
def refine(self, l, r):
    l = self._norm(l)
    r = self._norm(r)

    if l == self.BOT: return r
    if r == self.BOT: return l

    new_start = max(l[0], r[0])
    new_end = min(l[1], r[1])

    return self._norm((new_start, new_end))

def f_cmpop(self, op, left, c):
    left = self._norm(left)
    c = self._norm(c)

    # assume integers
    if op == '<':
        return (self.NINF, c[0] - 1), (c[0], self.PINF)
    elif op == '<=':
        return (self.NINF, c[0]), (c[0] + 1, self.PINF)
    elif op == '>':
        return (c[0] + 1, self.PINF), (self.NINF, c[0])
    elif op == '>=':
        return (c[0], self.PINF), (self.NINF, c[0] - 1)
    else:
        raise NotImplementedError(f'Operator {op}')
```

Partial code for f_cmpop and refine in the Signs domain

```
def refine(self, l, r):
    if self.lte(l, r): return l
    if self.lte(r, l): return r

    return self.TOP

def f_cmpop(self, op, left, c):
    # (abst of c, op) : (variable's true domain, variables false domain)
    abs_results = {(self.EQZ, '<'): (self.LTZ, self.GTZ),
                   (self.EQZ, '<='): (self.LTZ, self.GTZ),
                   (self.EQZ, '>'): (self.GTZ, self.LTZ),
                   (self.EQZ, '>='): (self.GTZ, self.LTZ),
                   (self.EQZ, '!='): (self.TOP, self.EQZ),

                   (self.GTZ, '>'): (self.GTZ, self.TOP),
                   (self.GTZ, '<'): (self.TOP, self.GTZ),
                   (self.GTZ, '<='): (self.TOP, self.GTZ),
                   (self.GTZ, '>='): (self.GTZ, self.TOP),
                  }

    key = (c, op)
    if key not in abs_results:
        raise NotImplementedError(f"{key} not implemented")

    return abs_results[key]
```

While: Example #1: Infinite Loop

```
x := 0
while(x >= 0) {
  x := x + 1
}
```

If we analyze this program abstractly using signs, using \sqcup^\sharp to combine states across loop iterations, as we did in the concrete execution, the analysis will reach a fixpoint, which can be used to terminate the analysis.

- $M^\sharp(x) = ([= 0] \sqcup^\sharp [>= 0] \sqcup^\sharp [>= 0]) = [>= 0]$

If we analyze this program abstractly using intervals, the analysis will not terminate.

- $M^\sharp(x) = [0, 0] \sqcup^\sharp [1, 1] \sqcup^\sharp [2, 2] \sqcup^\sharp [3, 3] \dots$

While: Example #2: Infinite Loop

```
x := 0
while(x <= 100) {
  if (x >= 50) {
    x := 10
  } else {
    x := x + 1
  }
}
```

If we analyze this program abstractly using signs, the analysis terminates as in the previous example

- $M^\#(x) = ([= 0] \sqcup^\# [>= 0] \sqcup^\# [>= 0]) = [>= 0]$

If we analyze this program abstractly using intervals, the analysis also terminates, but after 50 analysis iterations.

- $M^\#(x) = [0, 0] \sqcup^\# [0, 1] \sqcup^\# [0, 2] \sqcup^\# \dots \sqcup^\# [0, 50] \sqcup^\# [0, 50] = [0, 50]$

Observations

- Signs is a lattice with a finite height
 - $\sqcup^\#$ will eventually reach a fix point
- The Intervals lattice does not have a finite height
 - No such guarantees

Widening Operator

- Define an operator ∇ so that the sequence will explicitly reach a stationary point
- Soundness condition

$$\gamma(a_0) \cup \gamma(a_1) \subseteq \gamma(a_0 \nabla a_1)$$

- For all $(a_n)_{n \in \mathbb{N}}$, the sequence $(a'_n)_{n \in \mathbb{N}}$ is ultimately stationary:
 - $a'_0 = a_0$
 - $a'_{n+1} = a'_n \nabla a_n$

Code for Widening Operator for Intervals

```
def widen(self, x, y):
    # assume x is previous and y is current

    # compute a_n
    u = self.lub(x, y)

    if u[0] == x[0]:
        # stationary left
        return (u[0], u[1] if u[1] == x[1] else self.PINF)
    elif u[1] == x[1]:
        # stationary right
        return (u[0] if u[0] == x[0] else self.NINF, u[1])
    else:
        return u
```

abs_iter in code

```
def abs_iter(F_abs, M_abs, abstraction):
    R = M_abs
    while True:
        T = R
        if abstraction.dom.finite_height:
            R = abstraction.union(R, F_abs(R))
        else:
            R = abstraction.widen(R, F_abs(R))

        if R == T: break

    return T
```
